Module00: First Programs

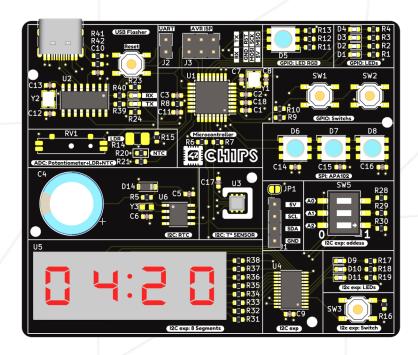

contact@42 chips.fr

Summary: Once upon a time, there was a little spectrum...

Version: 1

Chapter I

Prologue

For the entire piscine, you will use the provided devkit. It's based the ATMega328p microchip, a really nice microprocessor, completely in tune with the times

Exercises will be done in C. You will use the avr-gcc cross-compiler for the AVR architecture.

To write to the devkit's flash memory, you will use avr-objcopy & avrdude. You will use them with the arduino programmer with a 115200 baud rate.

The 2 most important documents for the whole piscine are:

- the ATmega328p's datasheet (653 pages of pure bliss);
- the devkit's schema.

Good luck to everyone, despite the intensity of the piscine, try not to get too wired! We're sure you'll realize your full potential!

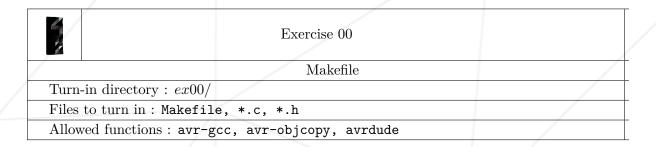

Chapter II

General instructions

Unless explicitly stated otherwise, the following instructions will be valid for all assignments.

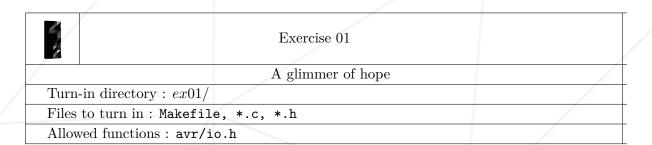

- The language used for this project is C.
- It is not necessary to code according to the 42 norm.
- The exercises are ordered very precisely from the simplest to the most complex. Under no circumstances will we consider or evaluate a complex exercise if a simpler one is not perfectly successful.
- You <u>must not</u> leave <u>any</u> files other than those explicitly specified by the exercise instructions in your directory during peer evaluation.
- All technical answers to your questions can be found in the datasheets or on the Internet. It is up to you to use and abuse these resources to understand how to complete your exercise.
- You <u>must</u> use the datasheet of the microcontroller provided to you and comment on the important parts of your program by indicating where you found the clues in the document, and if necessary, explaining your approach. Don't write long blocks of text, keep it clear.
- Do you have a question? Ask your neighbor to the right or left. You can ask in the dedicated channel on the Piscine's Discord, or as a last resort, ask a staff member.

Chapter III Setup

- The main.c file should contain a main() program that does not contain any instructions.
- Write a Makefile file with the all rule that executes the hex and then flash rules.
- The hex rule compiles the main.c file into main.bin with an F_CPU variable to select the microcontroller frequency. Then it generates the main.hex file from the main.bin file.
- The flash rule copies the main.hex file into the microcontroller's flash memory.
- The Makefile must also implement the clean rule that deletes the main.hex and main.bin files.

Chapter IV Let there be light

- You must write a program that turns on the LED D1 (PB0).
- You must use only AVR registers (DDRX, PORTX, PINX).

You must explain the function and values assigned to the registers in comments every time!

${\bf Embedded}$	pool
------------------	------

Module00: First Programs

	Exercise 02	
	Lumos	
Turn-in directory : $ex02/$		
Files to turn in: Makefile, *.c, *.h		
Allowed functions	s:avr/io.h. util/delav.h	/

- \bullet You must write a program that turns on LED D1 (PB0) when button SW1 (PD2) is pressed.
- \bullet When the button is released, the LED turns off.
- You must use only AVR registers (DDRX, PORTX, PINX).

Exercise 03

Day, Night, Day, Night

Turn-in directory : ex03/

Files to turn in: Makefile, *.c, *.h

Allowed functions: avr/io.h, util/delay.h

• You must write a program that reverses the state of the PB0 LED each time the SW1 button (PD2) changes from the released state to the pressed state.

• You must use only AVR registers (DDRX, PORTX, PINX).

Be careful of bounce effects!

Chapter V

Bonus: It's not rocket science!

	Exercise 04	
/	Binary Counter	
Turn-in directory : $ex04/$		
Files to turn in : Makefil	e, *.c, *.h	
Allowed functions : avr/	io.h, util/delay.h	

- You must write a program that:
 - o increments a value each time you press button SW1
 - $\circ\,$ decrements a value each time you press button SW2
 - o displays this value in binary on LEDs D1 D2 D3 and D4 permanently.
- You must use only the AVR registers (DDRX, PORTX, PINX)

If the 4 LEDs were on GPIO PBO, PB1, PB2, PB3, this exercise would be simpler.

Unfortunately, LED D4 is on PB4 instead of PB3 because PB3 is used for something else.

You will have to manipulate bits.
